

## General Algorithms on a DAG

Here DAG = Directed Acyclic Graph

At the highest level, a DAG algorithm typically looks like the following

Given graph  $G=(V,E)$  and start node  $s$ , to calculate a property “prop” for each node

- 1) for each  $v$  in  $V$ , initialize  $v.prop$
- 2) initialize  $s.prop$
- 3) determine topological order of  $G$  (may already be known)
- 4)  
for each  $u$  in  $V$ , taken in topologic order  
    for each  $v$  such that  $(u,v)$  is an edge  
        adjust  $v.prop$  based on  $u.prop$
- 5) (optional) for a specified target node  $t$ , return  $t.prop$

## More specifically for homework 2

In this case the topological order is  $1,2,3,\dots,N$ . Start node is node 1 and target node is node  $N$ . Here we will outline how to compute the longest path, which will be stored in an array  $LP[1..N]$ . The weight of edge  $(u,v)$  is stored as  $W[u,v]$ .

*initialize*

$LP[1]=0$

for  $i = 2$  to  $N$

$LP[i] = -\text{infinity}$

*loop*

for  $i = 1$  to  $N-1$

    for  $j=i+1$  to  $N$

        if  $(i,j)$  is an edge

            then  $LP[j] = \text{MAX}[ LP[j], LP[i]+W[i,j] ]$

            (update other properties here, if any)

*return*

print “longest path is”  $LP[N]$
